I want to get the name of the class it's located on. I don't want to get the specific name of the class, I only want the name of the class it's located on. Example. class Main{ CoinA coinA; CoinB coinB; } CoinA is on a different class from Main. How do i get the name of the class? A: Use this: public String getClassName(Class c) { String className = c.getName(); if (className.indexOf("\$\$") >= 0) { return className; } return "class " + className; } It will return the class name with the \$ at the start - but you may not be able to store that in a variable. If you are sure you want a blank class name it's much easier: public String getClassName(Class c) { return c.getName(); }

15. DOLQ: How to handle data validation in a react component I want to create a custom component that is written in react. This component is supposed to be a row in a grid. In the component, I want to verify that the data values coming from the redux store is valid. I also want to be able to pass it down to the component as props. However, I want the component to be able to handle if the data is invalid, and it should not be able to proceed if it is valid. I do not want it to be possible to insert the data that is coming from the redux store into the DOM. I'm not sure what the best solution is. Note: This is just a row in a grid, so all fields are optional. The data validation should only happen in the row, and the full data value should be used only when it is needed. A: I ended up using a Form component. It uses a Form component from CRA, and it was the easiest way to do it. I also needed to make sure the user has the right permissions, so I have it check that in the child component before sending it down. This invention relates generally to spiral wound turbine blades having a hollow interior and more particularly relates to a method of manufacturing the hollow interior. Conventional gas turbine engines include a compressor for compressing air which is mixed with fuel and ignited to form a high energy gas stream. The gas stream flows to a combustor where it is mixed with intake air and fuel and ignited to form a high energy gas stream. The gas stream expands in a turbine which is driven by the energy extracted from the gas stream. The turbine has multiple stages of airfoils including stationary vanes followed by rotating blades. Typically each airfoil has a hollow core from which a plurality of holes extend. The holes permit cooling air to be supplied to the airfoil or, in the case of the turbine airfoils, to a portion of the turbine casing within which the airfoil is disposed. During combustion of the gas stream, the latter portion of the turbine casing is at a relatively high temperature. The cooling air supplied to this portion of the turbine casing is used to prevent overheating and consequent hot corrosion of the casing. During use, the high temperature area of the turbine casing is typically supplied with cooling air from the compressor which is discharged at a relatively lower pressure than the inlet pressure 6d1f23a050
